Appendix 2

Results

*Analysis by stroke risk stratification at 12 and 36 months*

Cases at intermediate risk performed better than those at high (p=0.006) and low risk (p=0.022) in the logical memory test (delayed). A similar trend was seen for Rey figure recall, with intermediate risk cases scoring higher than both high (p=0.29) and low risk groups (p=0.014). However, for the telephone task, performance was significantly worse for high risk than low risk cases (p=0.028).
