## Supplementary Information

Qinglin Mei, Guojun Li and Zhengchang Su

## Supplementary Figures:

Fig. S1. Effects of the Gene Filter (GF) and PCA step on the accuracy (ARI) of RCSL in the 16 datasets. The ARI values were computed according to the annotated cell types.

Fig. S2. Comparison of running time of RCSL, RCSL without Gene Filter (GF) and RCSL without PCA.

Fig. S3. The running time of RCSL and RCSL2 on the 16 scRNA-seq datasets.

Fig. S4. The comparison of the accuracy of RCSL using KNN and RCSL using LSH for finding $k$-NNs using Euclidean distance, cosine angle distance and Hamming distance.

Fig. S5. Performance of the algorithms (RCSL, RCSL2, SC3, SIMLR, pcaReduce, k-means, CIDR, Seurat) on the 16 datasets measured by Normalized Mutual Information (NMI). The last panel shows the average NMI value for each algorithm over the 16 datasets.

Fig. S6. Performance of the algorithms (RCSL, RCSL2, SC3, SIMLR, pcaReduce, k-means, CIDR, Seurat) on the 16 datasets measured by Fowlkes-Mallows index (FM). The last panel shows the average FM value for each algorithm over the 16 datasets.

Fig. S7. Heatmap of Spearman's rank correlation matrix $\boldsymbol{S}_{s}$ and similarity matrix $\boldsymbol{S}$ in RCSL as well as the blockdiagonal similarity matrices $\boldsymbol{B}$ learned by RCSL, RCSL2, SIMLR in the indicated eight datasets. Cells are arranged according to their annotated types indicated by differently colored bars at the top and left of the matrices.

Fig. S8. 2-D PCA displays of the expression data matrices and matrices produced by RCSL in the 10 datasets.

Fig. S9. 2-D t-SNE displays of the expression data matrices and matrices produced by RCSL in the 16 datasets.

Fig. S10. 2-D UMAP displays of the expression data matrices and matrices produced by RCSL in the 16 datasets.

Fig. S11. Performance of RCSL and RCSL2 on 10 simulated datasets measured by adjusted rand index (ARI).

Fig. S12. Heatmap of Spearman's rank correlation matrix $\boldsymbol{S}_{s}$ and similarity matrix $\boldsymbol{S}$ in RCSL as well as the blockdiagonal similarity matrices $\boldsymbol{B}$ learned by RCSL and RCSL2 in the 10 simulated datasets. Cells are arranged according to their types indicated by differently colored bars at the top and left of the matrices.

Fig. S13. UMAP visualization of constructed MSTs (Minimum Spanning Trees) based on the clustering results of RCSL.

Supplementary Tables:
Table S1: Extended summary of the 16 scRNA-seq datasets used in this study.

## Supplementary Note:

## Procedure for constructing the block-diagonal matrix B

Note that Eq. (4) is difficult to solve since $\boldsymbol{L}_{B}=\boldsymbol{D}_{B}-\frac{\boldsymbol{B}^{T}+\boldsymbol{B}}{2}$, and $\boldsymbol{D}_{B}$ also depends on $B$, which leads to the constraint $\operatorname{rank}\left(\boldsymbol{L}_{B}\right)=N-C$ becomes a complex nonlinear constraint. Let $\sigma_{i}\left(\boldsymbol{L}_{B}\right)$ be the $i$-th smallest eigenvalue of $\boldsymbol{L}_{B}$. Since $\boldsymbol{L}_{B}$ is positive semidefinite, $\sigma_{i}\left(\boldsymbol{L}_{B}\right) \geq 0$. Thus the constraint $\operatorname{rank}\left(\boldsymbol{L}_{B}\right)$ $=N-C$ in problem (4) can be satisfied if $\sum_{i=1}^{C} \sigma_{i}\left(\boldsymbol{L}_{B}\right)=0$. Imposing a large enough value $\beta$, Eq. (4) can be transformed into an optimization problem,

$$
\begin{equation*}
\min _{\boldsymbol{B}}\|\boldsymbol{B}-\boldsymbol{S}\|_{1}+2 \beta \sum_{i=1}^{c} \sigma_{i}\left(\boldsymbol{L}_{B}\right) \text { s.t. } \sum_{j=1}^{N} b_{i j}=1, b_{i j} \geq 0 . \tag{5}
\end{equation*}
$$

Note that when $\beta$ is large enough, the sum of the $C$ smallest eigenvalues in $\boldsymbol{L}_{B}$ is forced to zero. Let $\boldsymbol{Y}_{N \times C}$ be the class indicator matrix, where $y_{i l}=1$ indicates that cell $i$ is assigned to the cluster $l$. CLR finds $\boldsymbol{B}$ by solving the following constrained minimization problem,

$$
\begin{equation*}
\min _{B, Y}\|\boldsymbol{B}-\boldsymbol{S}\|_{1}+2 \beta \operatorname{Tr}\left(\boldsymbol{Y}^{T} \boldsymbol{L}_{B} \boldsymbol{Y}\right) \text { s.t. } \sum_{j=1}^{N} b_{i j}=1, b_{i j} \geq 0, \boldsymbol{Y}^{T} \boldsymbol{Y}=\boldsymbol{I} \tag{6}
\end{equation*}
$$

To do so, we fix $\boldsymbol{B}$ and update $\boldsymbol{Y}$ : when $\boldsymbol{B}$ is fixed, problem (6) becomes,

$$
\begin{equation*}
\min _{\boldsymbol{Y}} \operatorname{Tr}\left(\boldsymbol{Y}^{T} \boldsymbol{L}_{B} \boldsymbol{Y}\right) \text { s.t. } \boldsymbol{Y} \in \boldsymbol{R}^{N \times C}, \boldsymbol{Y}^{T} \boldsymbol{Y}=\boldsymbol{I} \tag{7}
\end{equation*}
$$

The optimal solution of $\boldsymbol{Y}$ is the $C$ eigenvectors of $\boldsymbol{L}_{B}$ corresponding to the $C$ smallest eigenvalues. CLR then fix $\boldsymbol{Y}$ and update $\boldsymbol{B}$ : when $\boldsymbol{Y}$ is fixed, problem (7) can be transformed into,

$$
\begin{equation*}
\min _{b_{j}} \sum_{i, j=1}^{N}\left|b_{i j}-s_{i j}\right|+\beta \sum_{i, j=1}^{N}\left\|\boldsymbol{y}_{i}-\boldsymbol{y}_{j}\right\|_{2}^{2} b_{i j} \text { s.t. } \sum_{j=1}^{N} b_{i j}=1, b_{i j} \geq 0 \tag{8}
\end{equation*}
$$

where $\boldsymbol{y}_{i}$ is the class indicator vector of cell $i$. Note that problem (8) is independent for different $i$, so we can parallel the calculations by solving each $i$ independently, and rewrite (8) in the vector form for each $i$.

$$
\begin{equation*}
\min _{b_{i}}\left\|\boldsymbol{b}_{i}-\boldsymbol{s}_{i}\right\|_{1}+\beta \boldsymbol{b}_{i}^{T} \boldsymbol{f}_{i} \text { s.t. } \boldsymbol{b}_{i}^{T} \mathbf{1}=1, \boldsymbol{b}_{i} \geq 0, \tag{9}
\end{equation*}
$$

where $f_{i j}=\left\|y_{i}-y_{j}\right\|^{2}$, and $\boldsymbol{f}_{i}$ is a vector with the $j$-th element equal to $f_{i j}$ (similarly to $\boldsymbol{b}_{i}$ and $\boldsymbol{s}_{i}$ ). Problem (9) can be solved by using an iterative reweighted method described in (Nie, et al., 2016), which grantees converge to the optimal solution. Let $\boldsymbol{U}$ be the $N \times N$ diagonal matrix whose diagonal entry $u_{i i}=\frac{1}{2\left|\tilde{b}_{i j}-s_{i j}\right|}$, and the $\tilde{b}_{i j}$ is the current value. Then, problem (9) can be solved by iteratively solving the following problem:

$$
\begin{equation*}
\min _{\boldsymbol{b}_{i}} \operatorname{Tr}\left(\boldsymbol{b}_{i}-\boldsymbol{s}_{i}\right)^{T} \boldsymbol{U}\left(\boldsymbol{b}_{i}-\boldsymbol{s}_{i}\right)+\beta \boldsymbol{b}_{i}^{T} \boldsymbol{f}_{i} \text { s.t. } \boldsymbol{b}_{i}^{T} \mathbf{1}=1, \boldsymbol{b}_{i} \geq 0 \tag{10}
\end{equation*}
$$

It has been proved that this iterative method decreases the objective of (9) in each iteration and it will converge to the optimal solution (Nie, et al., 2010). Then the problem with a convex objective and linear constraints can be solved efficiently by the standard convex optimization method using
existing algorithm CLR. In our implementation, we set the largest number of iterations to 30 .
