Supplementary Figure S1  Percent of girls remaining premenarcheal, by category of sugar-sweetened beverage consumption. Sugar-sweetened beverages were calculated as the sum of non-carbonated fruit beverage (56%), non-diet soda (32%) and iced tea (10%). Values for questionnaire cycle and categorical variables categorized using quantiles (total energy, birthweight, height, activity, inactivity) were set to their median value, and values of other risk factors (race, maternal age at menarche, frequency of eating dinner as a family, household composition) were set to their mode in the study population.
