Supplemental Figure 2. Subjective ratings of urge to eat in 20 black (A) and 20 white (B) normal weight and obese women, before and after high and low glycemic load test meals. The urge to eat AUC (urge rating x 3 h) was significantly higher after the high compared to the low glycemic load meal (data not shown in graph, P=0.05); by visual inspection of the data, this effect appears to be greater in magnitude in white women than black women, although the glycemic load X race interaction was nonsignificant.
