Abstract

Leaf growth of many plant species shows rapid changes in response to alterations of the form and the level of N supply. In hydroponically-grown tomato (Lycopersicon esculentum, L.), leaf growth was rapidly stimulated by NO$_3^-$ application to NH$_4^+$ precultured plants, while NH$_4^+$ supply or complete N deprivation to NO$_3^-$ precultured plants resulted in a rapid inhibition of leaf growth. Just 10 $\mu$M NO$_3^-$ supply was sufficient to stimulate leaf growth to the same extent as 2 mM. Furthermore, continuous NO$_3^-$ supply induced an oscillation of leaf growth rate with a 48 h interval. Since changes in NO$_3^-$ levels in the xylem exudate and leaves did not correlate with NO$_3^-$-induced alterations of leaf growth rate, additional signals such as phytohormones may be involved. Levels of a known inhibitor of leaf growth, abscisic acid (ABA), did not consistently correspond to leaf growth rates in wild-type plants. Moreover, leaf growth of the ABA-deficient tomato mutant flacca was inhibited by NH$_4^+$ without an increase in ABA concentration and was stimulated by NO$_3^-$ despite its excessive ethylene production. These findings suggest that neither ABA nor ethylene are directly involved in the effects of N form on leaf growth. However, under all experimental conditions, stimulation of leaf growth by NO$_3^-$ was consistently associated with increased concentration of the physiologically active forms of cytokinins, zeatin and zeatin riboside, in the xylem exudate. This indicates a major role for cytokinins as long-distance signals mediating the shoot response to NO$_3^-$ perception in roots.

Key words: ABA, cytokinins, ethylene, flacca mutant, hydroponic culture, leaf growth, Lycopersicon esculentum, NH$_4^+$, NO$_3^-$, N deprivation.

Introduction

Nitrogen is a major nutrient for plant growth and is taken up by the roots from the soil preferentially as NO$_3^-$ or NH$_4^+$. Many plants show growth inhibition when NH$_4^+$ is supplied as the sole N source (Marschner, 1995). This NH$_4^+$-induced growth inhibition has been attributed to NH$_4^+$ toxicity. However, rapid inhibition (within 12–24 h) of shoot growth by NH$_4^+$ was detectable even when NH$_4^+$ toxicity was minimized by using moderate NH$_4^+$ concentrations (2 mM) in a buffered nutrient solution (Walch-Liu et al., 2000; Rahayu et al., 2001).

Various hormonal factors have been implicated in the regulation of plant growth responses to environmental stimuli: reduced shoot growth is frequently associated with elevated abscisic acid (ABA) concentrations as a result of certain environmental or nutritional stress conditions such as drought, salinity, soil compaction, and deficiencies of N, P, and K (Hartung et al., 1999). Sole NH$_4^+$ supply also resulted in increased ABA levels in castor bean (Ricinus communis) and pea (Pisum sativum) (Peuke et al., 1994; Zdunek and Lips, 2001). The potential role of ABA as an important regulator of shoot growth is further supported

by inhibitory effects in response to external ABA applications in well-watered plants (Watts et al., 1981; Robertson et al., 1990).

Cytokinins are involved in the regulation of cell division and cell expansion (Ivanova and Rost, 1998; Francis and Sorrell, 2001). Inhibition of shoot growth in tomato (Lycopersicon esculentum) and in tobacco (Nicotiana tabacum) grown with NH$_4^+$ as the sole N source was correlated with a sharp decline in cytokinin concentrations (Z+ZR) (Walch-Liu et al., 2000; Rahayu et al., 2001), a reaction that was rapidly reversible within 12–24 h. Evidence for the studies revealed that the expression of various genes in-
**NO₃ analysis**

Freeze-dried leaves or root material (5–10 mg) were extracted in 1 ml deionized water. The samples were then centrifuged at 16 000 g for 1 min. Nitrate was determined reflectometrically in the supernatant and in the xylem exudate (RQflex reflectometer, Merck, Darmstadt, Germany).

**Phytohormone analysis**

*Cytokinin and ABA*: Cytokinin and ABA concentrations in the xylem exudate and in freeze-dried leaves and roots (250 mg) were determined essentially as described by Bangerth (1994) and Bertling and Bangerth (1995) with some small modifications. Briefly, after conventional methanol (80%) extraction and evaporation of the extraction medium under vacuum, the redissolved extracts were frozen, thawed, centrifuged, and finally purified on a column combination of PVP, DEAE-Sephadex-A25, and Sep Pak C-18 cartridges. Differential elution of the hormones from this column combination allowed determination and quantification by radio-immuno assay (RIA) as described by Bohner and Bangerth (1988). All extractions and RIA-quantifications were replicated three times.

*Ethylene*: The two youngest fully unfolded leaves were cut off and discarded, the remaining stems including apex and just developing leaves were weighed and then immediately transferred into 50 ml syringes. The syringes were closed with a rubber septum. After incubation for 2 h at room temperature, a 0.5 ml sample was withdrawn from the syringe and analysed for ethylene by gas chromatography using an activated alumina column and a FID detector (GC: Shimadzu, Düsseldorf, Germany).

**Statistical analysis**

The statistical software Sigma Stat Version 2.03 (SPSS Inc., Chicago, Illinois USA) was used for analyses of variance. Comparisons between the means were conducted using the Student–Newman–Keuls test. Significant differences ($P < 0.05$) among N treatments (and tomato genotypes) were marked with different letters.

**Results**

**Leaf growth as affected by the external NO₃ concentration**

Since it was found that the presence of NO₃ stimulates leaf growth, the concentration-dependency of NO₃ supply on leaf growth was investigated further. The effects of 10 μM and 2 mM NO₃ on leaf growth rate, cytokinin status, and plant NO₃ levels were compared over 24 h using NH₄⁺-grown plants. Supply of 10 μM NO₃ to NH₄⁺-grown plants was sufficient to increase the leaf growth rate to approximate that of plants grown at 2 mM NO₃ (Table 1). The supply of 10 μM NO₃ already increased NO₃ concentrations in the xylem exudate to 50% of the level measured for plants with 2 mM NO₃ supply. However, leaf tissue concentrations reached only 4–5% of the 2 mM NO₃ treatment (Fig. 11).

The $Z+ZR$ concentrations in the plants supplied with 10 μM NO₃ also increased compared with NH₄⁺-treated plants, and in leaf and root tissue even reached significantly higher levels than at 2 mM NO₃ supply (Fig. 1A, B). While the concentrations of the $Z+ZR$ precursors, i-Ade+i-Ado, in the xylem exudate were similar at 10 μM and 2 mM NO₃ supply, leaf concentrations declined and root concentrations increased in the 10 μM NO₃ treatment (Fig. 1D, E, F).

**N-form-dependent short-term responses of leaf growth, cytokinins, and ABA**

As shown in previous studies with tobacco (Walch-Liu et al., 2000) and tomato (Rahayu et al., 2001), stimulation of leaf growth by NO₃ supply and inhibition by the application of NH₄⁺ are rapid responses occurring within 12–24 h. Time-courses of hormonal changes and NO₃ concentrations in plant tissues and xylem exudate as related to alterations of leaf growth were investigated in detail with two experimental set-ups:

*NO₃-induced stimulation of leaf growth*: Tomato plants precultured in NH₄⁺ were transferred to NO₃ for 2, 4, 12, and 24 h and then harvested at the same time of day to exclude diurnal variations. A transient increase in leaf growth rate was detectable after 4 h with a peak at 12 h of NO₃ supply (Fig. 2A). This was associated with corresponding changes in the $Z+ZR$ cytokinin fraction of leaves and xylem exudate (Fig. 2B). A rapid decline in ABA concentrations of leaves and xylem exudate within 2–4 h after commencing the NO₃ treatment preceded the stimulation of leaf growth. Thereafter, ABA levels partially recovered during the next 20 h (Fig. 2C). Nitrate concentrations in the xylem exudate increased within 2 h, reaching a saturation level of 30 mM 4 h after starting the NO₃ treatment. In leaf tissue, NO₃ concentrations increased continuously for the duration of the 24 h experimental period (Fig. 2D).

*Inhibition of leaf growth in the absence of NO₃*: Tomato plants were exposed to NH₄⁺ supply or complete N deprivation for 0, 2, 6, and 12 h after NO₃ preculture and harvested at the same time of day to exclude diurnal variations. Inhibition of leaf growth was already detectable for both N treatments 6 h after the withdrawal of NO₃ and was particularly obvious under N deprivation (Fig. 3A). The inhibition of leaf growth rate was preceded by declining concentrations of cytokinins ($Z+ZR$) in the xylem exudate and in young growing leaves, while the hormone levels in older leaves remained unaffected (Fig. 3B). Similar trends were noticeable for ABA concentrations (Fig. 3C). The NO₃ concentration in the xylem exudate had

already dropped from 14 mM to 0.3 mM 2 h after NO\textsubscript{3}\textsuperscript{-}/C\textsubscript{255} concentration withdrawal from the nutrient solution.

**NO\textsubscript{3}\textsuperscript{-}-induced oscillations in leaf growth and changes in translocation of cytokinins in the xylem**

Nitrate application over prolonged time periods (4–7 d) triggered an oscillation in leaf growth rate with a 48 h interval, which was not detectable in NH\textsubscript{4}\textsuperscript{+}-treated plants (Fig. 4A). This oscillation was associated with corresponding changes in Z+ZR levels in the xylem exudate (Fig. 4B), while Z+ZR concentrations in the leaf tissue did not show comparable changes (Fig. 4B). There was no detectable oscillation of ABA concentration in leaves, xylem exudate or NO\textsubscript{3}\textsuperscript{-} concentration in xylem exudates (Fig. 4C, D). The oscillation pattern was also not reflected in the xylem exudation flow rate (Fig. 4E).

**NO\textsubscript{3}\textsuperscript{-}-induced stimulation of leaf growth, xylem translocation of cytokinins, and ethylene production in the ABA-deficient tomato mutant 'flacca'**

The ABA-deficient mutant of tomato (flacca) and the near-isogenic wild-type line was used to assess the potential involvement of ABA in the regulation of N-form-dependent responses in leaf growth further. Compared with NH\textsubscript{4}\textsuperscript{+} nutrition, NO\textsubscript{3}\textsuperscript{-} supply increased plant biomass and leaf area in both the flacca mutant and the wild-type
line (Fig. 5A, B), although biomass production of the \textit{flacca} mutant was on average about 2.5 times less than the wild type (Fig. 5A, B). Increase in leaf growth of both tomato genotypes coincided with higher levels of Z+ZR in xylem exudate (Fig. 5D), while Z+ZR levels in the leaves were not affected by the N form (Fig. 5C). In wild-type plants, ABA concentrations increased in leaves and xylem exudate in response to NH$_4^+$ application, while ABA levels in the \textit{flacca} mutant were not affected by the supply of different N forms and were similar to wild-type plants supplied with NO$_3^-$ (Fig. 5E, F). Moreover, the \textit{flacca} mutant exhibited morphological symptoms characteristic of excessive ethylene production, such as curling of the shoot tip and leaf epinasty (results not shown). Accordingly, ethylene evolution originating from stems of the \textit{flacca} mutant was more than 700% of that of the wild-type plants (Table 2). However, ethylene production in both \textit{flacca} mutant and wild type was not affected by the supply of different N forms (Table 2).

**Discussion**

**Does NO$_3^-$ directly regulate leaf growth?**

A direct role of NO$_3^-$ as a signal molecule has been demonstrated for various physiological and morphological plant responses, such as the stimulation of lateral root elongation in nutrient-rich patches (Zhang \textit{et al.}, 1999) or NO$_3^-$-dependent gene expression of enzymes involved in

---

**Fig. 2.** Short-term effects of NO$_3^-$ on leaf growth and cytokinin, ABA, and NO$_3^-$ levels. Nitrate was supplied at a concentration of 2 mM N and for 2, 4, 12, and 24 h to tomato plants precultured on NH$_4^+$ for 3 d. Leaf growth rate (the value at t=0 represents the leaf growth rate [cm$^2$ h$^{-1}$] measured at continuous NH$_4^+$ supply in a time interval of 24 h) (A), concentrations of Z+ZR (B), ABA (C), and NO$_3^-$ (D) in leaves and xylem exudate were measured at 27 DAS. Data represent mean values and standard error of the means ($n=4$). ABA and Z+ZR concentrations in leaf material represent single measurements obtained from four pooled leaves, since leaf material of single leaves was insufficient for analysis.
N uptake (NO\textsubscript{3} + NO\textsubscript{2} transporters) and in N assimilation (glutamine synthetase/glutamate synthase) (Aslam et al., 1993; Redinbaugh and Cambell, 1993). However, in this study, the NO\textsubscript{3} -induced stimulation of leaf growth was not closely related to changes in NO\textsubscript{3} translocation in the xylem exudate or NO\textsubscript{3} concentrations in leaves. While the initially increased leaf growth rates declined again after 12 h of NO\textsubscript{3} supply, the NO\textsubscript{3} concentrations in the leaves continued to increase or reached a saturation level in the xylem exudate after 4 h (Fig. 2A, E). The NO\textsubscript{3} -induced increase in leaf growth also did not depend on a substantial NO\textsubscript{3} accumulation in the leaf tissue: a NO\textsubscript{3} supply of 10 \mu M stimulated the leaf growth rate comparable to 2 mM NO\textsubscript{3}, although NO\textsubscript{3} concentration in the leaves only reached 4–5% of that of plants supplied with 2 mM NO\textsubscript{3} (Table 1; Fig. 1G). These findings are in contrast with those of Scheible et al. (1997), who found a strong correlation between NO\textsubscript{3} concentration in the shoot and shoot/root ratio in tobacco. Furthermore, an oscillation in leaf growth induced by prolonged NO\textsubscript{3} application was not associated with corresponding changes in NO\textsubscript{3} concentrations of the xylem exudate (Fig. 4D).

Although the stimulation of leaf growth by traces of NO\textsubscript{3} in the external medium (10 \mu M) (Fig. 1) supports the idea of NO\textsubscript{3} as a 'signal molecule', the above data suggest that NO\textsubscript{3} itself may not be the direct trigger in mediating the N-form-induced changes in leaf growth. However, it cannot be excluded that the presence of NO\textsubscript{3} in the xylem or leaves may be necessary for the function of secondary signals, such as hormonal factors regulating leaf growth \textit{ad loci}.

**ABA is not involved in the regulation of NO\textsubscript{3}-induced stimulation of leaf growth**

Compared with NO\textsubscript{3} nutrition, long-term NH\textsubscript{4} supply increased the ABA levels in leaves and in the xylem exudate (Fig. 5E, F). This increase coincided with a reduction in plant biomass production (Fig. 5A), which could be mainly attributed to an inhibition of leaf area (Fig. 5B).

Similar findings were reported for castor bean (Ricinus communis; Peuke et al., 1994) and pea (Pisum sativum; Zdunek and Lips, 2001), supplied with NH\textsubscript{4} as the sole nitrogen source. Therefore, it was suggested that increased internal ABA accumulation might be responsible for the inhibition of shoot growth in plants continuously fed with NH\textsubscript{4}. However, in this study, short-term (2–12 h) supply of NH\textsubscript{4} or N deprivation revealed a rapid inhibition of leaf growth in NO\textsubscript{3} pre-cultured plants (within 6 h) (Fig. 3A), which was associated with declining levels of both cytokinins and ABA in the xylem exudate and in the tissue of young leaves (Fig. 3B, C). Thus, the decreased leaf growth rate could not be attributed to an inhibitory effect of ABA accumulation. Also the oscillation of leaf growth rate in plants continuously supplied with NO\textsubscript{3} was not related to corresponding changes in ABA levels in the xylem exudate and leaf tissue (Fig. 4A, C). Moreover, compared with NO\textsubscript{3} supply, NH\textsubscript{4}-nutrition also inhibited leaf growth of the ABA-deficient tomato mutant 'flacca' showing a low level of residual ABA production, which did not respond to the application of different N forms (Fig. 5B). Furthermore, daily applications of (10 mg l\textsuperscript{-1}) ABA completely 'normalized' the vegetative phenotype of flacca (F Bangerth, unpublished results).

Although exogenous ABA application shows inhibiting effects on shoot growth in some plants (Watts et al., 1981; Robertson et al., 1990), the results of the present study provide strong evidence that ABA is not directly involved in the signalling pathway of leaf growth, as ABA levels do not rapidly respond to the application of different N forms or to N deprivation. Increased ABA levels in plants continuously deprived of N or exclusively supplied with NH\textsubscript{4} may rather reflect a stress response related to metabolic disorders due to prolonged N deprivation or NH\textsubscript{4} supply (Peuke et al., 1994; Palmer et al., 1996; Fig. 5E, F).

**Ethylene is not involved in regulating NO\textsubscript{3}-induced stimulation of leaf growth**

Compared with wild-type plants, the flacca mutant was characterized by excessive ethylene production (Table 2).
Consistent with this finding, it was reported that ethylene production was enhanced in shoots of *flacca* (Tal et al., 1979; Sharp et al., 2000) and in whole plants of an ABA-deficient mutant of *Arabidopsis* (Rakinita et al., 1994) grown under well-watered conditions. In both wild-type plants and in the *flacca* mutant, ethylene production was not affected by the application of different N forms (Table 2).

Nitrate-induced stimulation of shoot growth was observed in the *flacca* mutant in the presence of high ethylene levels, and also in wild-type plants with low ethylene production (Fig. 5B; Table 2).

These findings suggest that, similar to ABA, ethylene is also not directly involved in regulating leaf-growth responses to application of different N-forms.

Fig. 4. Long-term effects of NO$_3^-$ and NH$_4^+$ on leaf growth and cytokinin, ABA, and NO$_3^-$ levels. Nitrate and NH$_4^+$ were supplied to tomato plants at a concentration 2 mM N. Leaf growth rate (A), concentrations of Z+ZR (B), ABA (C), and NO$_3^-$ (D) in xylem exudates and root pressure exudation rate (E) were measured at 30–34 DAS. Day 1 indicates the first day of measurements taken after the plants were long-term adapted for 3 d to the exposed N treatments. Data represent mean values and standard error of the means ($n=4$).
and Marschner, 1978; Palmer et al., 1996) already detectable 6 h after removal of NO$_3^-$ from the growth medium (Fig. 3). Inhibition of leaf growth was preceded by a drop in cytokinins in the xylem exudate and in young leaves, which was already detectable 2 h after the start of the N treatments (Fig. 3). Accordingly, NO$_3^-$ application resulted in a rapid stimulation of leaf growth within 4 h of supplying NO$_3^-$, and was associated with a corresponding increase in the Z+ZR translocation in the xylem (Fig. 2). The NO$_3^-$-induced increase in leaf growth and Z+ZR concentrations in the plant only required very low external NO$_3^-$ concentrations (10 μM) (Table 1; Fig. 1). Interestingly, Z+ZR concentrations in the leaves of plants supplied with 10 μM NO$_3^-$ were even higher than with 2 mM NO$_3^-$ supply. This increase in Z+ZR concentrations in the leaves could not be attributed to an increased Z+ZR supply by the xylem (Fig. 1A, C). Since the concentration of the Z+ZR precursor, i-Ade+i-Ado, declined in the leaves at 10 μM NO$_3^-$ supply to the same extent as the Z+ZR levels increased (Fig. 1D), it seems likely that the conversion rates of i-Ade+i-Ado at low NO$_3^-$ supply differ from conversion rates at high NO$_3^-$ supply.

Prolonged NO$_3^-$ application, but not NH$_4^+$ supply, induced oscillations in leaf growth rate with an interval of 48 h. These oscillations were associated with corresponding alterations in Z+ZR translocation in the xylem exudate, but not with changes in Z+ZR levels in leaves (Fig. 4A, B). These 48 h oscillations are distinct from the well-known 24 h circadian rhythms and may be determined by the properties of the system rather than by external factors (Volkenstein, 1983). As far as is known, cytokinins have not, to date, been implicated in either diurnal or longer period oscillations. The factors triggering the above fluctuations in Z+ZR in the xylem exudate are unknown and further specific experiments are needed to elucidate the regulatory mechanisms behind this system. Nitrate may act as a constant positive feed-forward signal leading to increased Z+ZR translocation in the xylem. Subsequently, an as yet hypothetical negative feed-back signal may temporarily repress Z+ZR synthesis in the roots and thus Z+ZR in the xylem exudate. Thereafter, the negative feed-back signal is reduced leading to a de-repression of the positive

Ethylene evolution (nl g$^{-1}$ h$^{-1}$)

**Are cytokinins mediating the NO$_3^-$ signal in leaf growth?**

In accordance with previous studies conducted with tomato and tobacco (Walch-Liu et al., 2000; Rahayu et al., 2001), NO$_3^-$-induced stimulation of leaf growth coincided with elevated Z+ZR levels in the xylem exudate and in the tissue of growing leaves (Figs 1, 2, 4, 5; Table 1). In addition, there are several reports for cotton (Gossypium hirsutum), stinging nettle (Urtica dioica), and barley (Hordeum vulgare) demonstrating that NO$_3^-$ supply increased cytokinin levels of previously N-starved plants (Wagner and Beck, 1993; Samuelson and Larsson, 1993; Yong et al., 2000). Similar to the sole NH$_4^+$ supply, N deprivation led to a rapid decrease in leaf growth (Fig. 3A, B; Sattelmacher et al., 1993; Samuelson and Larsson, 1993; Yong et al., 2000). Similar to the sole NH$_4^+$ supply, N deprivation led to a rapid decrease in leaf growth (Fig. 3A, B; Sattelmacher et al., 1993; Samuelson and Larsson, 1993; Yong et al., 2000).
feed-forward signal etc. A likely candidate for the negative feedback signal may be IAA via the basipetal IAA-transport pathway. This hormone has been shown repeatedly to suppress cytokinin biosynthesis in roots (Bangerth, 1994; Li et al., 1995) and thus could explain the above changes in cytokinin xylem exudate. Alternatively, this IAA/CK interaction could take place in above-ground tissue (Kaminek et al., 1997; Nordström et al., 2004).

All experiments conducted in this paper indicated a consistent association between Z+ZR translocation in the xylem exudate and leaf growth rate (Figs 1–5; Table 1). Further evidence for an involvement of cytokinins in NO$_3^-$-induced stimulation of leaf growth comes from studies with the direct leaf application of cytokinins, which could mimic the stimulating effect of NO$_3^-$ supply. (Kuiper, 1988; Kuiper and Staal, 1987). There is also evidence that NO$_3^-$-inducible genes responded much faster to cytokinin application than to NO$_3^-$ (Sakakibara et al., 1998; Taniguchi et al., 1998). These genes encode protein homologues to bacterial two-component regulators, which act as signal transduction intermediates in different signalling pathways. Alterations in xylem translocation of Z+ZR may induce corresponding changes of Z+ZR concentrations in the leaf apoplast. Recently, a cytokinin receptor in plants was reported. This receptor may sense apoplastic cytokinins via an extracellular cytokinin-binding domain (Yamada et al., 2001; Inoue et al., 2001). Downstream of the cytokinin-sensing system, cytokinin-induced response regulators may control the expression of genes which are involved in leaf growth. A role for cytokinins in the regulation of leaf growth by promoting cell expansion (Ulsvskov et al., 1992; Downes et al., 2001) and cell division (Soni et al., 1995) were previously reported. To conclude, from this and the present work, it is very likely that cytokinins are involved as a ‘mediating hormonal signal’ in the NO$_3^-$-induced stimulation of leaf growth.

From an evolutionary point of view, the observed rapid alterations of leaf and shoot growth depending on the form and amount of N supply may be part of the well-known adaptive responses of plant growth to nutrient limitation, characterized by increased root/shoot ratios. Promotion of root growth at the expense of shoot growth by sensing NO$_3^-$ concentrations in the rhizosphere could be an advantage for the exploitation of a larger soil volume under conditions of N deficiency, but also in the presence of nutrients with limited mobility in soils, such as NH$_4^+$. It seems rather unlikely that NO$_3^-$ by itself is the primary signal in the investigated process. Similarly ABA and ethylene are not involved in the NO$_3^-$-induced increase in leaf growth rate. To prove these statements, further investigations have to be conducted including the interaction of NO$_3^-$ with other phytohormones in the shoot, characterization at the molecular genetic level, and analysis of mutants and/or transgenic plants with altered expression of the related genes.
