Manganese chloride (MnCl₂) is capable of stimulating luteinizing hormone releasing hormone (LHRH) secretion in adult male Sprague-Dawley rats through the activation of the hypothalamic nitric oxide/cyclic guanosine monophosphate (cGMP)/protein kinase G pathway. The present study aimed to determine the involvement of specific neurotransmitters involved in this action. Our results indicate that dopamine, but not glutamic acid and pyroglutaminals, mediates the MnCl₂-stimulated secretion of LHRH from medial basal hypothalami in vitro, as well as increases the activity of nitric oxide synthase. Furthermore, a biphasic response was observed in that gamma aminobutyric acid (GABA) release was also increased, which acts to attenuate the MnCl₂ action to stimulate LHRH in that gamma aminobutyric acid (GABA) release was also increased, nitric oxide synthase. Furthermore, a biphasic response was observed in that gamma aminobutyric acid (GABA) release was also increased, which acts to attenuate the MnCl₂ action to stimulate LHRH synthase (NOS) and leads to production of nitric oxide (NO). In turn, NO activates the NO/cGMP/PKG dependent pathway in adult animals following exposure to high chronic levels of Mn⁺².

Key Words: luteinizing hormone; prolactin; dopamine; gamma aminobutyric acid; glutamic acid; prostaglandin E; nitric oxide.

Manganese (Mn⁺²) is an essential metal which acts as a cofactor for many enzymes and therefore, plays important biological functions (Keen et al., 1984). Nevertheless, high doses of Mn⁺² exert toxic effects in the brain (Yamada et al., 1986) and the accumulation of Mn⁺² in the basal ganglia produces an irreversible neurological syndrome similar to Parkinson’s disease (Cotzias, 1958; Mena, 1974). High levels of this metal can cause alterations in development as well as reproductive dysfunction (Grey and Laskey, 1980; Laskey et al., 1982), and Mn⁺² deficiency produces impairment of growth and reproduction in rats of both sexes (Boyer et al., 1942; Smith et al., 1944). It was reported that chronic administration of Mn⁺² at low doses to female rats resulted in increased serum levels of puberty-related hormones such as luteinizing hormone (LH), follicle-stimulating hormone (FSH), and estradiol, and advanced the time of vaginal opening (Pine et al., 2005). Also, it was found to accelerate daily sperm production and efficiency of spermatogenesis in prepubertal males (Lee et al., 2006). These effects were explained by a hypothalamic action of the metal that facilitates the secretion of prepubertal luteinizing hormone releasing hormone (LHRH) in both sexes (Lee et al., 2006, 2007; Pine et al., 2005).

The LHRH released from the hypothalamus into capillaries of the hypothalamic portal vessels is carried to the hypo-physyal gonadotropes where it stimulates the release of LH and FSH (McCann, 1982). Glutamic acid (GA) and catecholamines are important neurotransmitters involved in LHRH release (Rettori et al., 1994; Ojeda et al., 1979). GA stimulates the noradrenergic neuronal terminals resulting in the release of norepinephrine (NE). This in turn activates the α₁-adrenergic receptors located on nitridergic neurons, thus, increasing intracellular calcium (Ca²⁺), which activates nitric oxide synthase (NOS) and leads to production of nitric oxide (NO) (Rettori et al., 1994). NO diffuses and activates soluble guanylate cyclase, therefore, generating cyclic guanosine monophosphate (cGMP) which causes an activation of protein kinase G (PKG) and the exocytosis of LHRH (Karanth et al., 2004). We have shown that MnCl₂ increases LHRH secretion from medial basal hypothalamus (MBH), at least in part, by activating the NO/cGMP/PKG dependent pathway in adult male rats (Prestifilippo et al., 2007). Another pathway that can also be activated by NO is cyclooxygenase (COX). Activation of this pathway results in the production of prostaglandin E₂ (PGE₂), which, through cyclooxygenase, is capable of decreasing cAMP/protein kinase A (PKA) and thus, induces exocytosis of LHRH (Rettori et al., 1992, 1993). Thus, one of the aims of the present study is to discern whether MnCl₂ can also affect this COX signaling pathway.

In order to better understand the mechanism of the Mn⁺² action to influence the above pathway(s), it is important to...
analyze potential actions and interactions between Mn\(^{+2}\) and specific neurotransmitters. Interestingly, stimulation of dopamine (DA) type 2 receptors causes an increase in intracellular Ca\(^{+2}\), which activates the NOS/NO system (McCleskey et al., 1987; Melis et al., 1994), resulting in increased LHRH release. Furthermore, NO is also capable of inducing the release of gamma aminobutyric acid (GABA), a recognized inhibitory neurotransmitter of LHRH release (Seilicovich et al., 1995). Therefore, assessing potential interactions between these two neurotransmitter systems may help discern more about how this metal affects reproductive hormone secretion. (See schematic diagram of the interactions between different neurotransmitters that could take place and participate in LHRH release, Fig. 1.)

**MATERIAL AND METHODS**

**Animals.** Male rats of the Sprague-Dawley strain (220–250 g) were kept in group cages in an animal room having a photoperiod of 14 h of light (05.00–19.00 h) and a temperature of 22°C–24°C. Animals had free access to laboratory chow and tap water. The experimental procedures reported here were approved by the Animal Care Committee of the Center of Pharmacology and Botanical Studies of the National Council for Research of Argentina and carried out in accord with the guidelines of the National Institutes of Health.

**In vivo studies.** The rats were implanted with a cannula into the lateral cerebral ventricle, under tribromoethanol (3.5%, 1 ml/100 g animal body weight, i.p.) anesthesia, using a stereotaxic instrument and coordinates from the atlas. The correct localization of the cannula in the ventricle was confirmed at the end of the experiment. The experiments were performed a week after the implantation of the cannula. Twenty-four hours before the experiment, an indwelling catheter was placed into the right external jugular vein and advanced to the right atrium for the collection of blood samples. The day of experiment, conscious, freely moving rats were divided into two groups of 10 animals each. After the collection of the first blood sample (0.5 ml), the rats were microinjected intracerebroventricularly (i.c.v.) during 1 min with 5 \(\mu\)l of sterile saline (control group) or 10 \(\mu\)g of MnCl\(_2\)/5 \(\mu\)l sterile saline. Every 30 min thereafter, blood samples (0.5 ml) were obtained until 120 min following the i.c.v. injections. Each blood sample was immediately replaced with 0.5 ml of saline containing 50 IU of heparin/ml. After centrifugation, the plasma was stored frozen at –20°C until the determination of plasma LH and prolactin by radioimmunoassay (RIA).

**In vitro studies.** After decapitation and removal of the brains, the MBH were dissected by making frontal cuts just behind the optic chiasm, extending dorsally 1.0 mm, a horizontal cut extended from this point caudally to just behind the pituitary stalk. Longitudinal cuts were made 1.0 mm lateral to the midline bilaterally. All incubations were carried out in a Dubnoff shaker (50 cycles per min; 95% O\(_2\)/5% CO\(_2\) at 37°C. The hypothalami (seven to eight for each group) were preincubated individually in glass tubes in 500 ml of Krebs-Ringer bicarbonate-buffered medium (NaCl 124.40 mM, KCl 4.98 mM, NaHCO\(_3\) 24.88 mM, CaCl\(_2\) 1.50 mM, MgCl\(_2\) 1.42 mM, KH\(_2\)PO\(_4\) 1.25 mM containing 0.1% glucose, pH 7.4). After this preincubation (15 min) the medium was discarded and replaced with fresh medium alone or containing the substances to be tested. The incubation continued for 30 min. At the end of the incubation period the media were removed and the tissues were homogenized and submitted to appropriate extraction procedure and stored at –20°C until the respective assays were conducted.

**Radioimmunoassays.** Plasma LH and prolactin levels were measured by RIA. Rat LH antisemur (NIDDK-anti-rLH-S-II), antigen (NIDDK-rLH-1,9), and reference preparation (NIDDK-rLH-RP-3); and rat PRL antiserum (NIDDK-anti-rPRL-S-9), and reference preparation (NIDDK-rPRL-RP-3) were purchased from the NIH Pituitary Hormones and Antisera Center, Harbor, UCLA, Medical Center, Torrance, CA. The interassay variations for these assays were 6.6% and the intra-assay variations were 3.6%. All samples were measured in duplicate and the results were expressed as ng of LH or prolactin per ml of plasma. LHRH release into the incubation media was measured by RIA utilizing a highly specific LHRH antisemur kindly provided by Ayala Barnea (University of Texas Southwestern Medical Center, Dallas, TX). The intra-assay coefficient of variation ranged from 7.3% and the interassay coefficient of variation was 8.9%. The sensitivity of the assay was 0.2 pg/100 μl. The data were expressed as pg LHRH released/mg protein/MBH.

To determine hypothalamic PGE content, tissues were homogenized individually in 1.5 ml of ice cold ethanol 100%, centrifuged at 20,000 × g for 15 min at 4°C and the supernatant collected and evaporated in a Speed-Vac. Medium were extracted by tree fold of ethyl acetate and evaporated in a Speed-Vac. The residues were resuspended with RIA buffer and the determination of PGE by RIA was performed by using a rabbit antiserum from Sigma Chemical Co. (St Louis, MO). The intra-assay and interassay coefficients of variation for PGE were 8.2 and 12%, respectively. The results were expressed as pg of PGE contained per MBH.

**Determination of DA release.** DA was extracted from the incubation media, where the MBH were incubated, with Tris-HCl buffer (2M, pH 8.7) and 3,4-dihydroxybenzylamine hydrobromide (100 ng/ml), as internal standard and dehydrated alumina. After shaking for 10 min, samples were centrifuged at 19,000 × g for 10 min. Pellets were washed three times with deionized water, centrifuged and 200 μl of H\(_2\)PO\(_4\) (0.1M) was added. After shaking for 2 min, samples were centrifuged and supernatants from the media were filtered and injected in an analytical column (Luna 5 μ C-18, 4.6 × 250 mm, Phenomenex) maintained at 37°C. DA was determined by high performance liquid chromatography with electrochemical detection and registered with an integrator. The mobile phase was prepared with NaH\(_2\)PO\(_4\) (100mM), heptanesulfonic acid (32x414) inhibition or decrease.

![FIG. 1. Schematic diagram of the interactions between different neurotransmitters and LHRH release. For explanation, see Introductory section. Luteinizing hormone releasing hormone neuron, LHRH; dopamine neuron, DA n; GABA\(_A\) receptor, GABA\(_A\); glutamic acid neuron, GA n; NMDA receptor, NMDA r; norpinephrine neuron, NE n; \(\alpha_1\)-adrenergic receptors, \(\alpha_1\)-r; guanylate cyclase, GC; GTP; cGMP; adenylate cyclase, AC; ATP; cAMP; arachidonic acid, AA; portal vessel, PV; +, stimulation or increase; –, inhibition or decrease.](image-url)
(1 mM), ethylenediaminetetraacetic acid (0.5 mM), and 6% acetonitrile, pH 3.0. Quantification and recovery calculation was performed using the Gilson 712 System Controller Software. The data were expressed as ng of DA released per mg of protein/MBH.

Determination of NOS activity. Determination of NOS activity was performed by a modification (Canteros et al., 1995) of the 14C-arginine method of Bredt and Snyder (1989). After the incubation period (30 min) the MBH were immediately homogenized in 0.5 ml of N-(2-hydroxyethyl) piperazine-N′-2-ethanesulfonic acid (HEPES) (20 mM, pH 7.4) with addition of CaCl2 (1.25 mM) and DL-dithiothreitol (DTT, 1 mM). The reaction was started by adding NADPH (nicotinamide adenine dinucleotide phosphate, reduced) (120 μM) and 200,000 dpm of 14C-arginine (360 mCi/mmol) to the homogenates. The tubes were incubated for 15 min at 37°C in a Dubnoff metabolic shaker (50 cycles per min and 95%O2/5%CO2 atmosphere). At the end of this incubation period, the tubes were immediately centrifuged at 10,000 × g for 10 min at 4°C. The supernatants were immediately applied to individual columns containing 1 ml of Dowex AG 50 W-X8 200 mesh sodium form, and washed with 2.0 ml of double distilled water. All collected fluid from each column was counted for 14C-citrulline activity in a scintillation counter. Because NOS converts arginine into equimolar quantities of citrulline and NO, the data were expressed as pmol of NO produced per MBH per min.

Measurements of radioconversion of 14C-arachidonic acid to prostanoids. These measurements were performed by chromatography of ethyl acetate extracts and counting of the labeled prostanoids as previously reported (Franchi et al., 1994). The area of each of the radioactive peaks corresponding to authentic prostanoids was calculated and expressed as a percentage of the total radioactivity of the plates per MBH.

Determination of GABA and GA release. The concentration of GABA and GA were determined after derivatization with phenylisothiocyanate by high performance liquid chromatography and UV detection at 254 nm, as previously described (Jarry et al., 1992). The drugs used did not interfere with the derivatization process. The mobile phase was prepared with sodium acetate buffer (0.57M) and 10% acetonitrile, pH: 6.5. The data were expressed as pmol per mg of protein/MBH.

Chemicals. LHRH for iodination and standards were purchased from Peninsula Laboratories, Inc., Division of Bachem (San Carlos, CA). Iodine-125 for iodination was purchased from New England Nuclear Life Science Product (Hercules, CA), and the 14C-arginine-monohydrochloride 360 mCi/mmol and 14C-arachidonic acid 56 μCi/mmole were from Amersham Pharmacia (Buckinghamshire, HP, UK).

Statistical analysis. Experiments were repeated at least twice employing seven to eight animals per group in each experiment. All data are expressed as the mean ± SEM. Comparisons between groups were performed by using a one-way ANOVA followed by the Student-Newman-Keuls multiple comparison test for unequal replicates. Student’s t-test was used when comparing two groups. Differences with p values < 0.05 were considered significant.

RESULTS

Effect of MnCl2 on Plasma LH Levels

We have previously reported that MnCl2 can cause LHRH release from the MBH in adult male rats (Prestifilippo et al., 2007) and this peptide controls the pituitary secretion of LH and FSH. In order to determine the in vivo effect of MnCl2 on plasma LH levels, rats were stereotaxically implanted with a cannula into the lateral cerebral ventricle and received a single i.c.v. injection of MnCl2 (10 μg/5 μl saline). Results show that MnCl2 increased the plasma LH levels at 30 min (p < 0.05) postinjection. The hormone remained elevated at 60 min (p < 0.05), then declined to preinjection levels by 90-min postinjection (Fig. 2). Control rats injected with saline did not show a change in LH secretion at any of the time points. Calculation of the areas under the respective curves of plasma LH for 120 min further demonstrated the MnCl2-induced increase (p < 0.05) in plasma LH levels (Fig. 2, inset).

Role of CaCl2 in MnCl2-Induced LHRH Release and NOS Activity

In order to evaluate whether MnCl2 is able to replace calcium, we assessed the effect of MnCl2 in vitro on LHRH release determined by RIA and NOS activation assessed by the conversion of 14C-arginine into 14C-citrulline and NO in the presence or absence of CaCl2 in the incubation medium. MnCl2 (500 μM) increased LHRH release (p < 0.05; Fig. 3A) and NOS activity (p < 0.01; Fig. 3B) in the presence of CaCl2 (1.25 mM). These effects were abolished in calcium free medium (Figs. 3A and 3B).

Effect of MnCl2 on DA and GA Release from MBH

The control of LHRH release is exerted by different neurotransmitters including DA and GA. Therefore, with the purpose of determining whether MnCl2 could affect their secretion, we evaluated the release of DA and GA from the MBH by high-performance liquid chromatography (HPLC). Results indicate that MnCl2 (500 μM) caused a marked increase (p < 0.001) in DA release during a 30 min incubation (Fig. 4A). Conversely, at the same time we observed a decrease (p < 0.05) in the release of GA (Fig. 4B).
Participation of DA in the MnCl₂-Induced Release of LHRH

In order to demonstrate that the augmentation in DA release exerted by MnCl₂ is involved in LHRH secretion, we assessed the effect of haloperidol, a well-known DA receptor antagonist. Our results indicate that haloperidol (1 μM) blocked the MnCl₂-stimulated LHRH release from the MBH and did not alter the basal release of LHRH (p < 0.05; Fig. 5A). In addition, the MnCl₂ stimulation of NOS activity was blocked by haloperidol (p < 0.01; Fig. 5B), and there was a modest reduction in NOS activity noted in tissues incubated in haloperidol alone (p < 0.05; Fig. 5B).

Effect of MnCl₂ on Plasma Prolactin Levels

It is well documented that hypothalamic DA inhibits prolactin release from the pituitary gland. To further demonstrate the involvement of MnCl₂ on DA release, we evaluated the in vivo effect of MnCl₂ on plasma prolactin levels determined by RIA. One injection of MnCl₂ (10 μg/5 μl saline, i.c.v.) reduced plasma prolactin levels compared with saline-injected controls at 30 (p < 0.05), 60 (p < 0.01), and 90 min (p < 0.05), returning to basal levels at 120 min (Fig. 6). The area under the 120 min curve of prolactin secretion confirmed that MnCl₂ caused a decrease in prolactin levels (p < 0.05) compared with the saline-treated group (Fig. 6, inset).

Actions and Interactions of MnCl₂ and GABA on LHRH Release

The LHRH release can be inhibited by GABA. Therefore, we studied the effect of MnCl₂ on GABA release from the MBH by HPLC. Results demonstrate that MnCl₂ increased (p < 0.001) GABA release (Fig. 7A). Because GABA inhibits LHRH release, we next studied the effect of MnCl₂ in the presence of bicuculline (10 μM), a GABAA receptor antagonist, on LHRH release. Bicuculline enhanced MnCl₂-induced LHRH release (p < 0.001) but had no effect on basal secretion (Fig. 7B), suggesting that GABA attenuates the stimulation of LHRH release induced by MnCl₂.

Effect of MnCl₂ on Hypothalamic Prostaglandins Involved in LHRH Release

We have demonstrated that the hypothalamic content of PGE was decreased (p < 0.01) following exposure to MnCl₂ in vitro (Fig. 8A). Coincidently, MnCl₂ inhibited hypothalamic COX activity measured by the radioconversion assay of 14C-arachidonic acid to 14C-labeled prostanoids. MnCl₂ diminished 14C-6-keto-PGF1α (p < 0.01), 14C-PGE2 (p < 0.001), 14C-tromboxane (TxB2, p < 0.001), and did not change 14C-PGF2α as compared with control groups (Fig. 8B). Furthermore, the inhibition of COX by indomethacin did not block the MnCl₂-induced increase in...
Collectively, these results suggest that the PGE/cAMP/PKA pathway does not participate in the release of LHRH induced by MnCl₂.

**DISCUSSION**

The results of the present study demonstrate that MnCl₂ stimulates LHRH release from MBH. This acute stimulatory effect on the in vitro release of LHRH was supported by the increase in plasma LH levels shown in vivo after a single i.c.v. injection of MnCl₂. Also, MnCl₂ is capable of stimulating DA secretion and NOS activity in the MBH. Because it was shown that DA can induce NOS/NO (Melis et al., 1994, 1996), and based on the important role of NO in the control of LHRH (Rettori et al., 1993) this suggests that DA/NO activation may mediate the MnCl₂-stimulated secretion of LHRH. Previously, DA in low concentrations has been shown to enhance LHRH release from MBH of male rats in vitro (Negro-Vilar et al., 1979). Also, it was shown recently that MnCl₂ stimulates LHRH release from prepubertal female (Pine et al., 2005) and male (Lee et al., 2006) rats, and that this was due to the activation of guanylyl cyclase and subsequent stimulation of the cGMP/PKG pathway (Lee et al., 2007).
In the present study, we assessed whether DA/NO interactions were involved in the MnCl₂-induced release of LHRH. Support for the involvement of this pathway was revealed by the fact that the specific DA receptor antagonist, haloperidol, blocked the stimulatory effect of MnCl₂ on LHRH release and NOS activity. Interestingly, it has been shown that autoxidation of DA is potentiated by Mn²⁺ in comparison to other biologically important divalent cations, suggesting that this autoxidation of DA is associated with increased generation of free radicals (Donaldson et al., 1981).

Further evidence for a DA involvement regarding hypothalamic actions of MnCl₂ is supported by what is known about DA release and its effect on prolactin secretion from the anterior pituitary gland. DA is released from the nerve terminals of the tuberoinfundibular dopaminergic neurons of the hypothalamus and acts on D₂ receptors located on pituitary lactotrophs to inhibit prolactin release (Neill and Nagy, 1994). In this regard, we showed that MnCl₂ stimulated DA release from hypothalami incubated in vitro, and that plasma prolactin levels were markedly decreased following the central administration of the metal. Interestingly, with regard to DA release, it has been shown that the MnCl₂-induced increase in DA release from striatal synaptosomes is due to its permeation through presynaptic voltage-dependent Ca²⁺ channels, suggesting that Mn²⁺ may be a potential substitute for Ca²⁺ in the exocytotic process (Drapeau and Nachshen, 1984). However, our results using hypothalamic tissue indicate that this was not the case, because without Ca²⁺ in the incubation medium, MnCl₂ was ineffective in stimulating both LHRH release and NOS activity.

Prostaglandins can act as cellular messengers in LHRH release in response to NE (Ojeda et al., 1982; Rettori et al., 1992). In our experiments, MnCl₂ decreased COX activity, as well as hypothalamic PGE content. Also, we found that MnCl₂ decreased the release of GA, as described similarly in the hippocampus (Takeda et al., 2003). We have shown previously that GA stimulates LHRH release via the NE/NO pathway (Kamat et al., 1995). Thus, our results showing that MnCl₂ caused significant decreases in hypothalamic GA and PGEs demonstrated that this pathway is not involved in Mn²⁺ control of LHRH secretion.

In addition to revealing a MnCl₂ action to stimulate DA-induced LHRH release, we have also uncovered an action of the metal on the inhibitory transmitter, GABA. This is an important inhibitory neurotransmitter involved in LHRH secretion and we previously reported that NO stimulates release of GABA from MBH in vitro in order to attenuate the pulsatile secretion of LHRH driven by NO (Seilicovich et al., 1995). In the present work, we observed that MnCl₂ stimulated GABA release from MBH in vitro. The evidence for attenuation of LHRH release by GABA was confirmed when hypothalamic fragments were incubated with MnCl₂ in the presence or absence of bicuculline, a GABA_A receptor blocker. This showed that when the GABA action was blocked, an enhanced release of LHRH occurred.

Although more research is needed, the information attained thus far suggests that MnCl₂ can cause differential effects on reproductive systems depending upon the dose of the metal in relation to the sex and age of the animals at the time of exposure.
We showed previously that MnCl₂ stimulates LHβ release in immature female rats by a NO-independent mechanism. In this regard, the MnCl₂ directly activated guanylyl cyclase at a dose which was ten fold less than that used in the adult males from the present study (Lee et al., 2007). Furthermore, chronic low dose administration of MnCl₂ continued to release LHβ/LH in immature female and male rats, eventually causing precocious pubertal development (Lee et al., 2006; Pine et al., 2005). Taken together, these results prompted us to suggest that although MnCl₂ may play a beneficial role to stimulate LHβ release at the time of normal puberty, it could also be harmful in that it may cause precocious pubertal development if an individual is exposed to low but elevated levels of the metal too early in life. Interestingly, it has also been shown that exposure to high levels of MnCl₂ may play a role in the growth and development of the reproductive system (Grey and Laskey, 1980; Laskey et al., 1996). Thus, it is clear that MnCl₂ acutely induces LHβ release, we suggest that the ability of the metal to induce GABA secretion in adult males may represent a neurotoxic effect to ultimately inhibit LHβ secretion, perhaps following a more prolonged exposure. This may provide an explanation for reports showing an overall suppression of reproductive function in adults following chronic exposure to high doses of MnCl₂ (Boyer et al., 1942; Grey and Laskey, 1980; Laskey et al., 1982; Smith et al., 1944).

FUNDING

Agencia Nacional de Promoción Científica Tecnológica (BID 1728 OC-AR PICT 03/14264); the Consejo Nacional de Investigaciones Científicas y Técnicas (PIP 6149); and the Agencia Nacional de Promocion Cientifico Tecnologico (BID 1728 OC-AR PICT 03/14264); and the Consejo Nacional de Investigaciones Científicas y Técnicas (PIP 6149). Taken together, these results prompted us to suggest that although MnCl₂ may play a beneficial role to stimulate LHβ release at the time of normal puberty, it could also be harmful in that it may cause precocious pubertal development if an individual is exposed to low but elevated levels of the metal too early in life. Interestingly, it has also been shown that exposure to high levels of MnCl₂ may play a role in the growth and development of the reproductive system (Grey and Laskey, 1980; Laskey et al., 1996). Thus, it is clear that MnCl₂ acutely induces LHβ release, we suggest that the ability of the metal to induce GABA secretion in adult males may represent a neurotoxic effect to ultimately inhibit LHβ secretion, perhaps following a more prolonged exposure. This may provide an explanation for reports showing an overall suppression of reproductive function in adults following chronic exposure to high doses of MnCl₂ (Boyer et al., 1942; Grey and Laskey, 1980; Laskey et al., 1982; Smith et al., 1944).
